

HOW MANY SIGNIFICANT FIGURES ARE USEFUL FOR PUBLIC RISK ESTIMATES?

6th IAASS Conference

Session 25: Launch Safety –
Part 3

By: Paul D. Wilde, Ph.D., P.E. and Jim Duffy
Date: May 2013

Federal Aviation
Administration

Outline

- **Purpose**
- **Background on Uncertainties**
 - **Definitions**
 - **History of 321**
- **Relationship of EC point estimate to mean when epistemic uncertainties are accounted for**
- **Examples**
- **Precedent in nuclear power risk**

Purpose

- **Recommend the use of only one significant figure as the default for reporting Expected Casualties (EC) results to a decision-maker unless there are other analyses, data, or circumstances to justify the use of an additional significant figure**
 - For FAA: when making a license determination (baseline risk analysis) and for day-of-launch collective risk analyses used to determine if a launch can be initiated
 - Focus is on new and mature orbital ELVs

Definitions

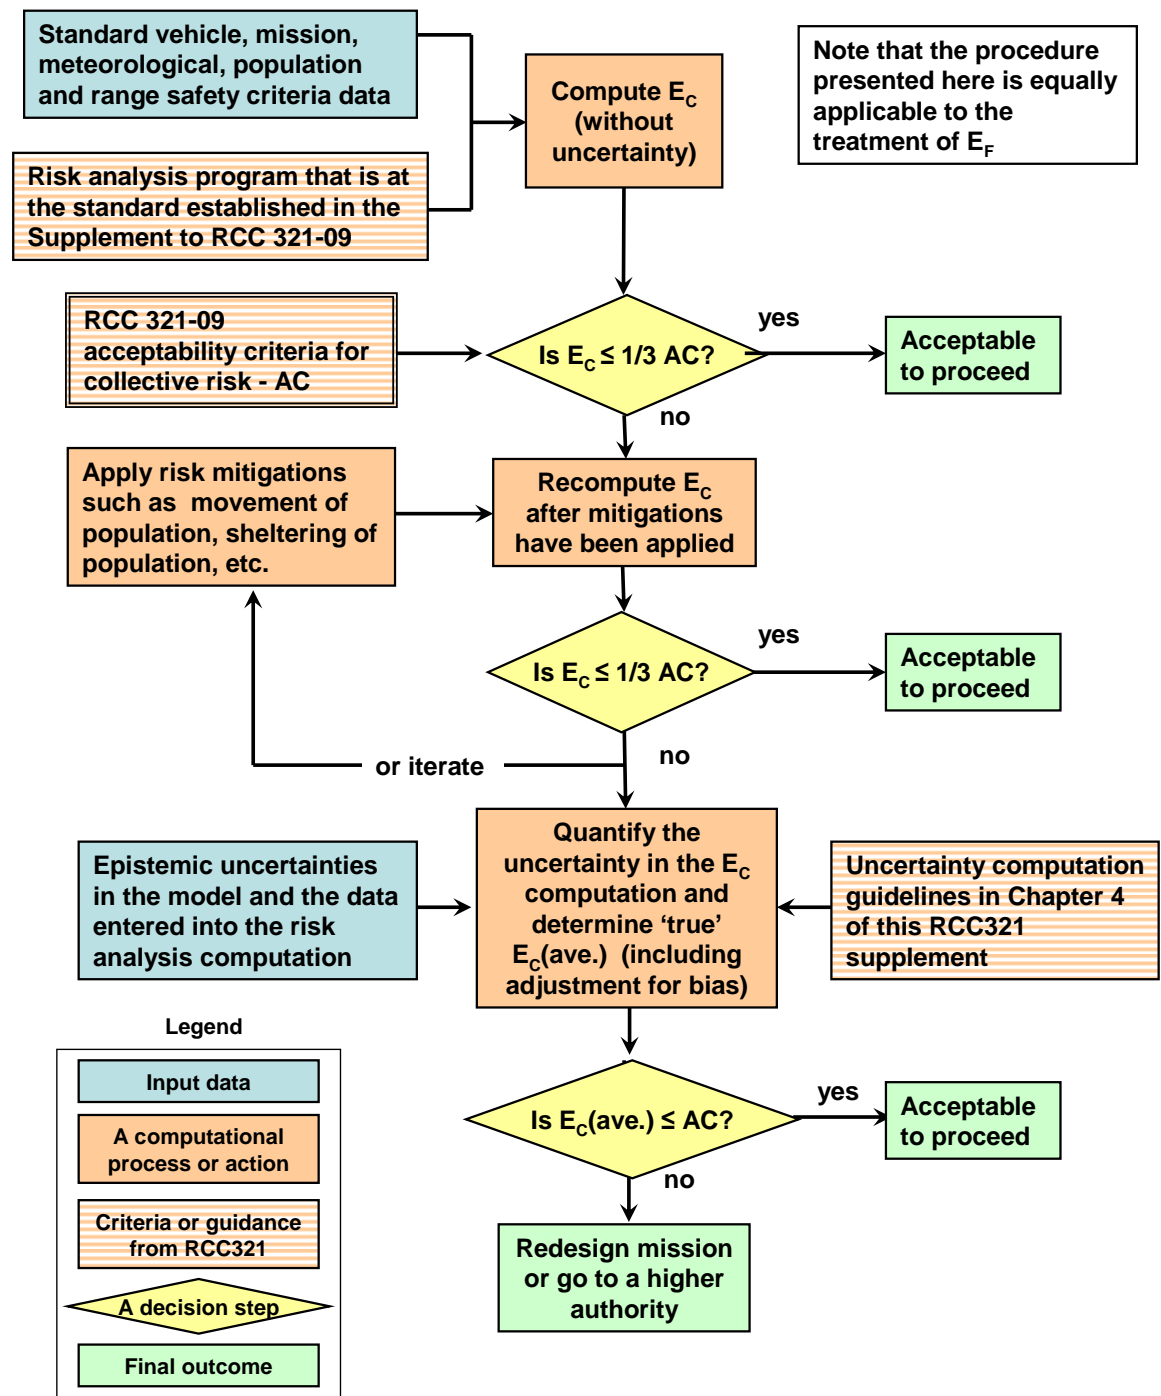

- **Expected Casualties (per 321)** - The mean number of casualties predicted to occur as a result of an operation if the operation were to be repeated many times.
- **Aleatory uncertainty** – random uncertainty that cannot be removed by improving the model, e.g. wind. A typical risk analysis program has models for the aleatory uncertainty and the resulting E_C is an average loss considering aleatory uncertainty.
- **Epistemic uncertainty** – uncertainty in the computed result due to the inability of the mathematical/ computer model to simulate the actual process perfectly.
- **Bias** – a shift in the computed result from the true value due to typically “conservative” modeling decisions.

RCC 321 History of Uncertainty Treatment

- **321-07 first to acknowledge uncertainty (see notes pages), but deferred treatment to future.**
 - “Ninety percent confidence bounds describing the uncertainty in the computed risk can have a range of several orders of magnitude.”
- **321-10 acknowledged that there is uncertainty in the estimates of the risk of launches and considered if/how this could affect the selection of launch acceptability criteria.**
 - Produced a flow diagram to guide when uncertainties should be assessed quantitatively

Flow Diagram for the Launch Risk Acceptability Process Considering Uncertainty

– Adopted in the RCC 321-10 Standard

Relationship of EC point estimate to mean when epistemic uncertainties are accounted for

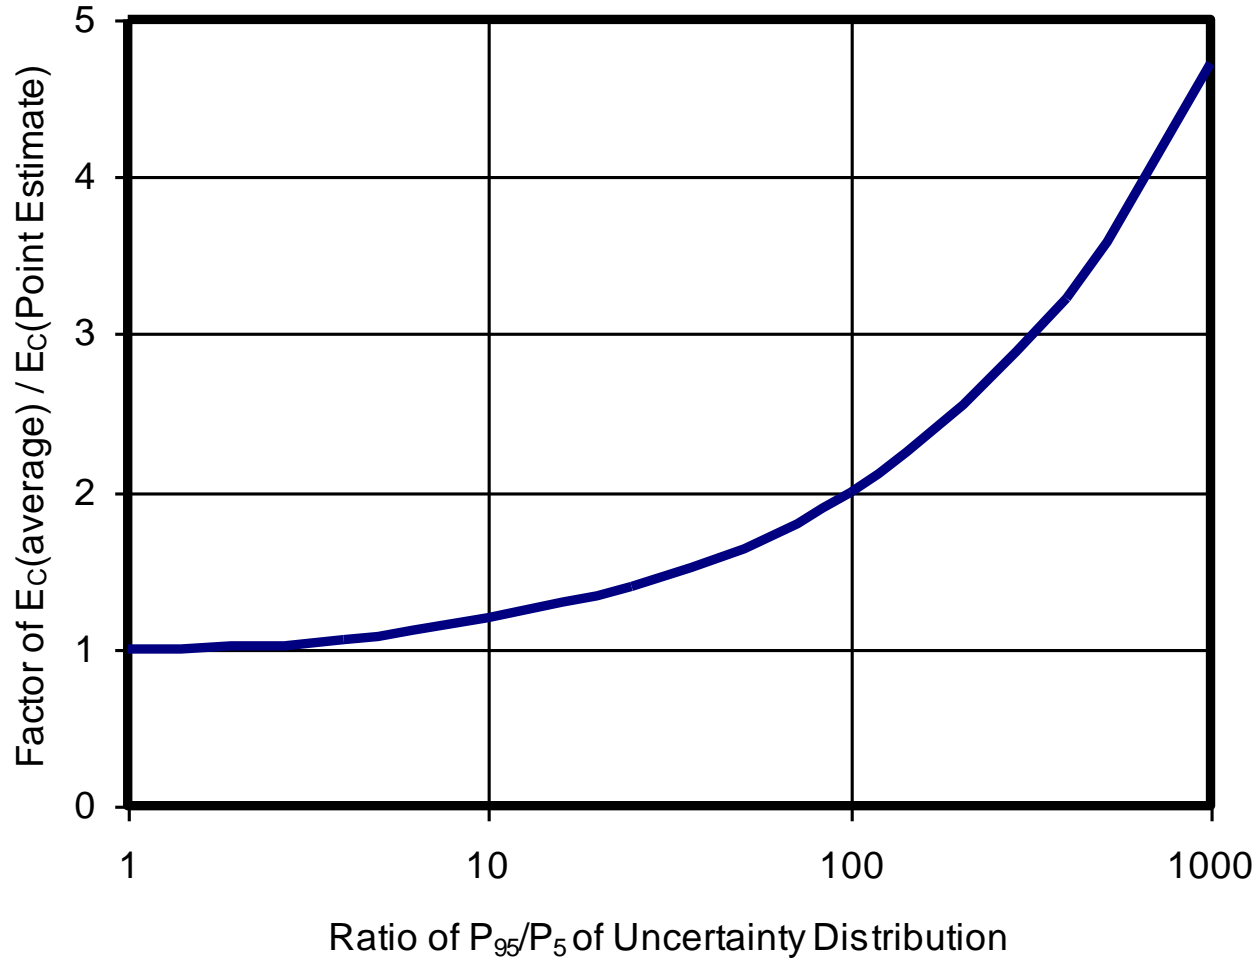

- There is a difference between the point estimate of E_C made by a single run of a risk analysis program and the average E_C resulting from averaging the results of many E_C s from an uncertainty analysis.
 - **The average is always larger than the point estimate of the E_C unless biases are accounted for**

The Relationship Between Median (Point Estimate) and Mean (Average) for a E_C Uncertainties Modeled with a Lognormal Distribution

| Ratio of value at P_U to the value at P_L for 95% Confidence | $E_C(\text{avg.})/E_C(\text{median or pt. est.})$ |
|--|---|
| 1 | 1 |
| 4 | 1.06 |
| 25 | 1.40 |
| 100 | 1.99 |
| 400 | 3.22 |
| 1000 | 4.72 |

Note: The actual uncertainty distribution could vary from a lognormal distribution. These ratios are only indicative of the ratios to be expected.

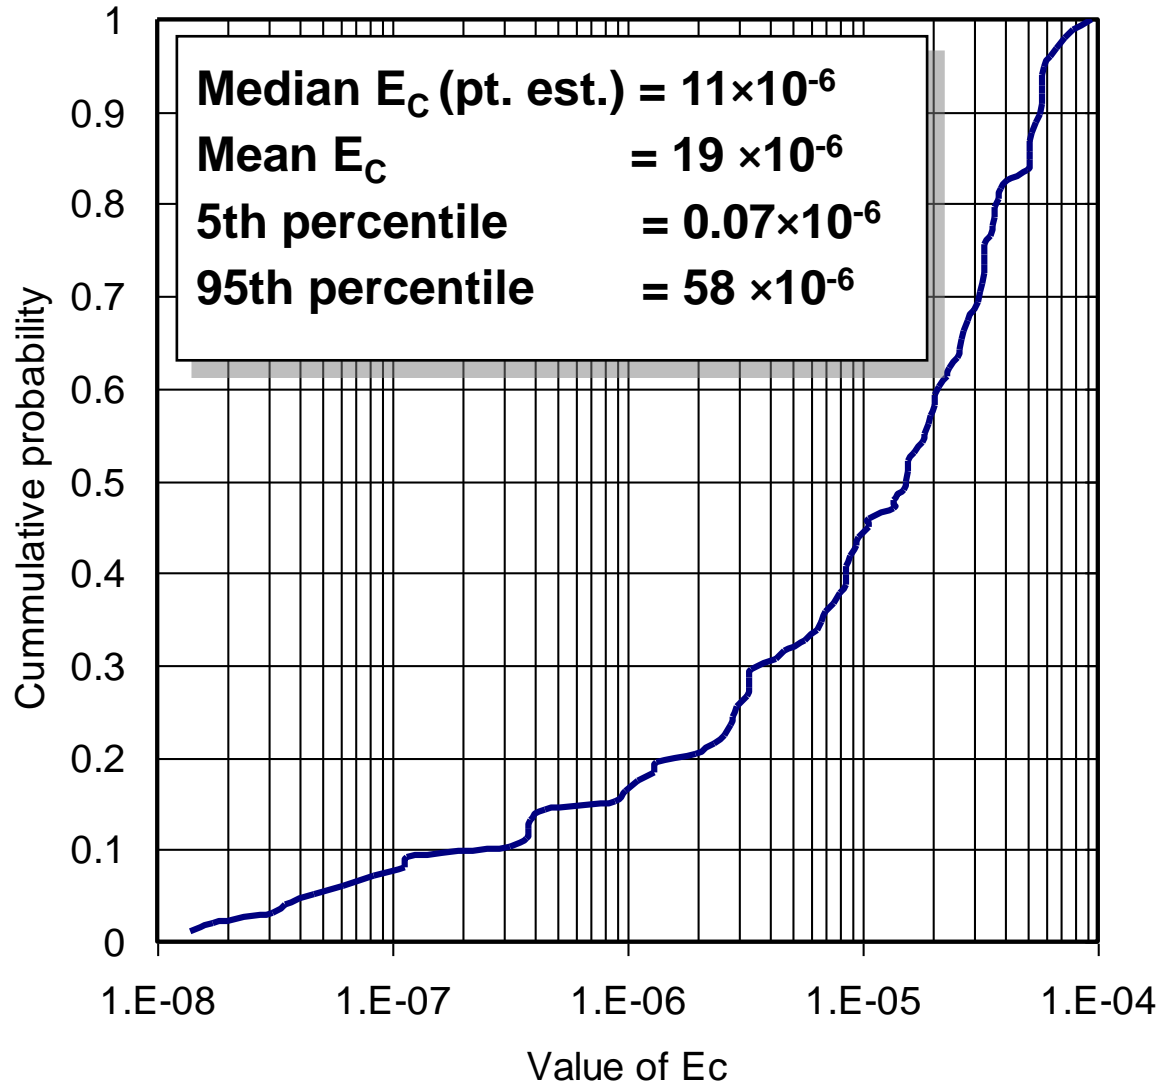

The Relationship Between Median (Point Estimate) and Mean (Average) for a E_C Uncertainties Modeled with a Lognormal Distribution

Uncertainty and Mean EC Issue

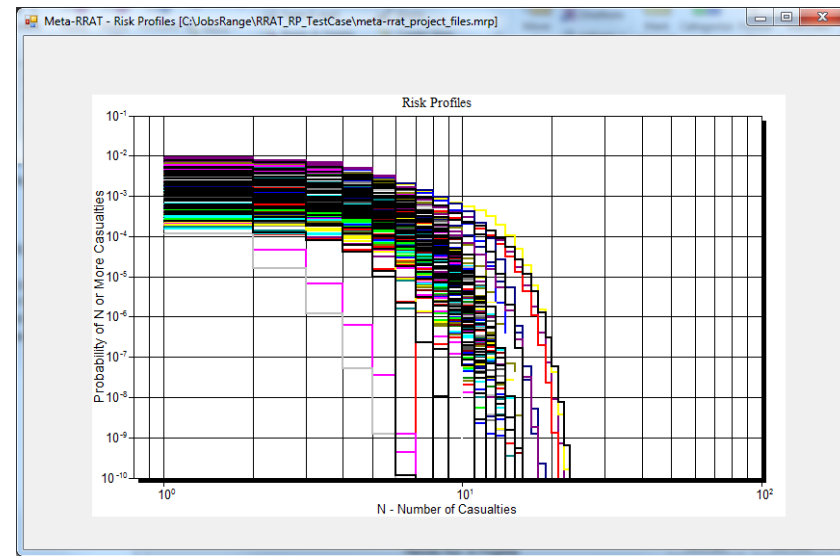

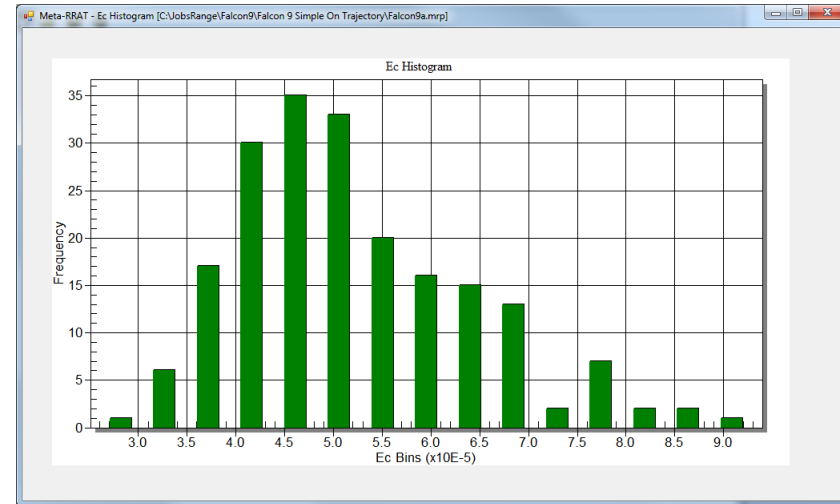

- **If uncertainty is computed, the average E_C resulting from the uncertainty analysis will often about twice the point estimate of the E_C**
 - **This would mean that, effectively, vehicles would have twice the risk and a higher likelihood of launches being held with current criteria, UNLESS the biases in the model have been accounted for.**

Atlas V Launch Area Risk for VAFB

Meta-RRAT Overview

- Meta-RRAT is a PC-based risk analysis tool with a Monte Carlo approach to estimate the uncertainty and bias in the results of a normal RRAT analysis
- Provides a GUI interface to facilitate input of a set of sources of uncertainty
 - **Model uncertainties and bias**
 - **Wind profiles**
 - **Debris lists**
 - **Failure probability as a function of time in flight**
- Produces risk profiles and total E_C histogram plots to reveal effects of uncertainties and biases
- Computes a distribution for the E_C in linear and log space

Top Level Modeling Uncertainties

- **CV for Dispersion**
 - Uncertainty in the total footprint size for each fragment group
- **CV for Population**
 - Uncertainty in the number of people in each population center
- **Debris Lists**
 - Input multiple debris lists or input estimated uncertainty in casualty area that would result from variations in the debris list.
- **Yield Uncertainty**
 - This models uncertainty in the explosive yields from solid and liquid propellants of various types
- **Human Vulnerability**
 - Uncertainty in the modeled vulnerability of humans to debris impact
- **Inert debris sheltered casualty area model uncertainties**
 - Each roof type can have it's own uncertainty
- **Vulnerability to explosive debris from structural failures**
- **Vulnerability to explosive debris from window breakage**

Over-flight Uncertainty Analysis for Modeling Uncertainties Only (No POF or debris list uncertainties)

RRAT baseline mission $E_C = 60E-6$ (no modeling uncertainties in baseline)

Results

Arithmetic (Linear Space)

Mission Ec: 5.428E-05

Std Dev: 1.216E-05

Cov.: 22.40 %

+1 Sigma: 6.644E-05

-1 Sigma: 4.213E-05

Geometric (Log Space)

Mission Ec: 5.300E-05

Std Dev (orders of mag): 1.243E00

Cov.: 24.30 %

+1 Sigma: 6.588E-05

-1 Sigma: 4.264E-05

Plot Risk Profiles

Plot Ec Histogram

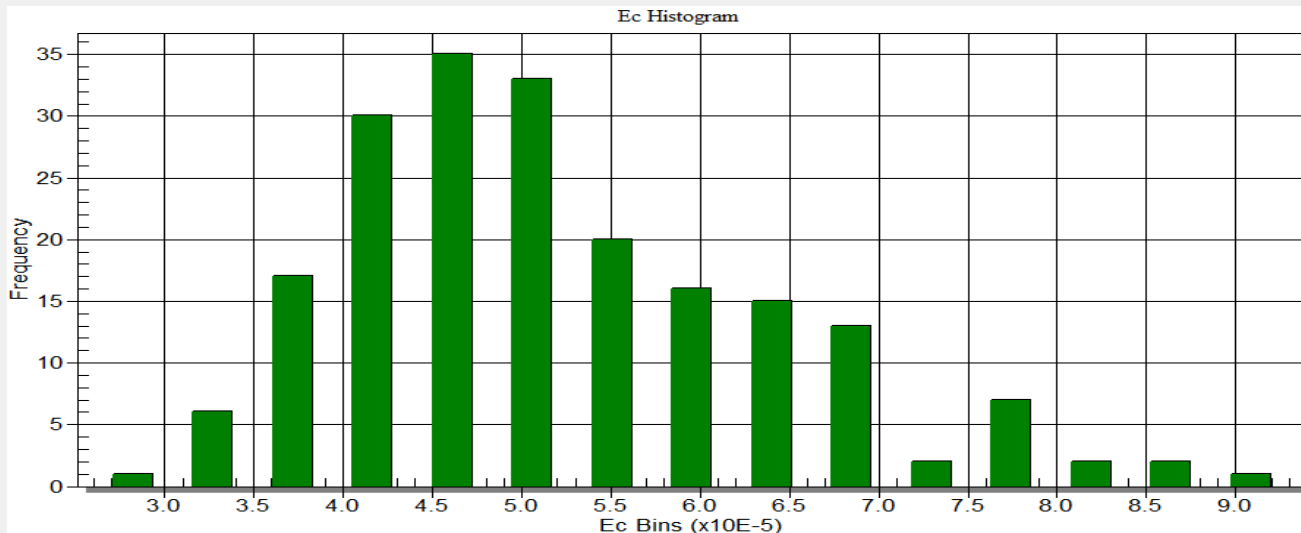

With model uncertainties

mean EC is ~10% lower (biases)

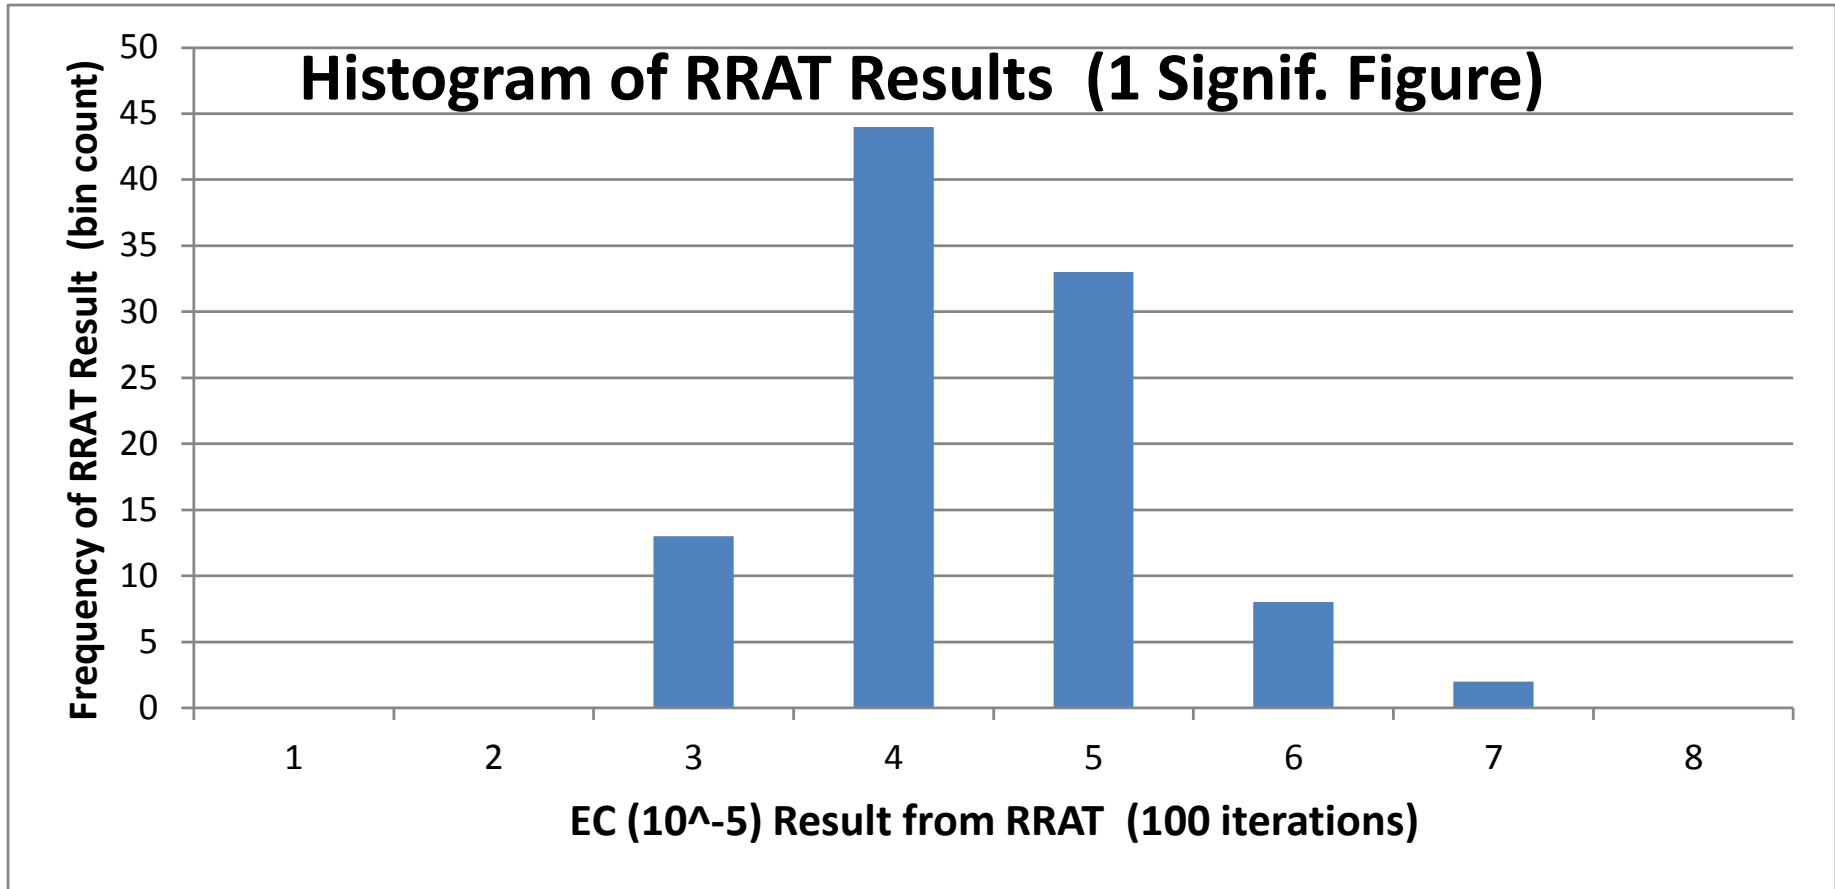

99 percentile 2x above mean

1percentile 3x below mean

| | | 0.07 | 0.15 | 0.23 | 0.32 | 0.41 | 0.50 | 0.59 | 0.68 | 0.77 | 0.85 | 0.93 |
| | | 0.00 | 0.02 | 0.08 | 0.16 | 0.24 | 0.33 | 0.42 | 0.52 | 0.62 | 0.73 | 0.85 |

After 4 flights with 2 failures: credible POF range for 5th launch is 0.21 – 0.79, with a reference value of 0.50

Key Point for Public Risk Uncertainty

- **Dominant source of uncertainty depends on the specifics of the launch/re-entry and risks of concern.**
- **For example:**
 - Columbia conditional ground risk (given the event, location, and time) uncertainty was dominated by the fraction of people outside.
 - Uncertainty in risk to people in an aircraft assumed present during Columbia event likely dominated by the uncertainty in the consequence of an impact.
 - Uncertainty in EC for aircraft from a launch/re-entry at an unspecified time of day dominated by air-traffic density
 - New ELV launch risks uncertainty often dominated by POF

Precedents in Nuclear Power Industry

- The Nuclear Regulatory Commission was forced to recognize uncertainty.
 - They had used an acceptability standard of 1×10^{-6} which was used against their risk predictions. 1×10^{-6} was an aspired safety goal.
 - They acknowledged the uncertainty and raised the aspired safety goal to 10×10^{-6} .
 - They use the average from the risk uncertainty distribution for their measure of risk against criteria
